CRAFT bearings Quality Control Laboratory

All CRAFT bearings production is guaranteed because it is tested twice to meet high standards: first in the factory and second time in the CRAFT bearings Quality Control Laboratory in Kaunas, Lithuania.

The CRAFT bearings Quality Control Laboratory was established in 2012 with the help of University of Technology.

We conduct all necessary tests with the latest measurement and quality-assurance systems utilizing high-quality and precise measuring equipment:

- Bearing Life (Longevity)
- Bearing Waviness
- Noise and Vibration
- Radial and Axial clearance
- Hardness
- Geometry
- Metal structure
- Roundness
- Roughness
- Grease leakage
- Dimension measurement
- Spectroscopic analysis

Roughness, Roundness and Form analysis

Characterization of surface topography is important in applications involving friction, lubrication and wear. Generally it has been found that friction increases with average roughness.

An accurate knowledge of the expected bearing life is essential to the proper selection of ball bearings. Bearings principally fail due to fatigue if they are properly lubricated, mounted and sealed against dirt entry. Fatigue strongly correlates with the surface roughness. One of the most important fundamental forms for engineering components is the circular cross-section. Circular forms arise in many applications, particularly in bearing surfaces. Roughness, roundness and bearing forms' testers are critically important elements in the development of precision-tolerance capabilities. For such measurements, we use the German-made OPTACOM surface measuring machine VC-10-EL.

Noise and vibration testing for bearings

A noisy application might be caused by wavy bearing components, local defects in the rings and balls or by dirt particles in the bearing. While basic requirements for a bearing such as stiffness, load capacity, speed limit and service life play a critical role in applications, low noise and vibration are even more important.

All of these quality issues for bearings can be tested with the following bearing vibration equipment: SN-X, S9912-X. High-tech analyses and measurements such as frequency analysis and further advanced analyses pinpoint faults. Spectral masks help to optimize the bearing performance in the particular customer application. With some experience, the measurement results of these machines can also be used by experts to detect imperfect manufacturing steps. The introduction of a worldwide calibration system enables vibration equipment to operate according to international standards.

Hardness Testing for bearings

Hardness is the property of a material that enables it to resist plastic deformation, usually by penetration. Hardness is not an intrinsic material property dictated by precise definitions in terms of fundamental units of mass, length and time. A hardness property value is the result of a defined measurement procedure. The hardness test of bearing surfaces is conducted with the SHR-3000 tester using the Rockwell hardness test method. The Rockwell hardness test method consists of indenting the test material with a diamond cone or a hardened steel ball indenter. The indenter is forced into the test material under a preliminary minor load of usually 150 kg. When equilibrium has been reached, an indicating device which follows the movements of the indenter and responds to changes in depth of penetration of the indenter is set to a datum position.

Axial & Radial Internal Clearance testing for bearings

A bearing's internal clearance is defined as the total distance in which one bearing ring can be moved in relation to the other in the radial direction (radial internal clearance) or in the axial direction (axial internal clearance). Too little or too much internal clearance will significantly influence factors such as heat, vibration, noise and fatigue life. In extreme applications that produce high or low temperatures, this clearance needs to be considered in the overall design to compensate for thermal expansion and contraction of housings and shafts. Bearings having an internal clearance other than Normal are identified by the suffixes C1 to C5.

Materials testing for bearings rings and rolling elements

There are essentially two choices for the material used in ball bearings - chrome steel or stainless steel. Since the material plays a major part in the performance of a bearing in any given application, it is very important to use the correct material. Note that the specified material applies to the load-bearing components only - the rings and the balls. The retainer and the shields, if used, are usually made from a different material and are subject to separate specifications. Chrome steel is the standard material used for ball bearing applications where load capacity is the main consideration. The machinability of this steel is excellent, giving smooth, low-noise raceway finishes together with superior life.

A chrome steel material is recommended in applications where corrosion is not a factor. Stainless steel is the standard material for miniature and instrument ball recommended in applications where corrosion is not a factor. Stainless steel is the standard material for miniature and instrument ball bearings where corrosion resistance is more important than load capacity. These materials have evolved in response to different manufacturing and application needs. It is important to note that the actual material used is generally determined by the manufacturer and cannot be specified by the user.

The bearing's metal structure is easily determined using the analytical instrument SPECTROMAXx made in Germany. This instrument is able to monitor the carbon signal during the pre-spark phase and to recognize the existence and proportion of free graphite in the sample.

Dimension measuring for bearings parts

The Universal Length Measurer (ULM) is a kind of length measuring instrument that integrates fine mechanics, an optical system and electrical parts into an organic whole. This instrument is used for direct measurement and comparative measurement for dimensions of parts and components. It also offers additional equipment for carrying out various special measurements.

Bearing “tolerances”, or dimensional accuracy and running accuracy, are regulated by ISO standards. For dimensional accuracy, these standards prescribe the tolerances necessary when installing bearings on shafts or in housings. Running accuracy is defined as the allowable limits for bearing runout during operation. Dimensional accuracy constitutes the acceptable values for bore diameter, outer diameter, assembled bearing width and bore diameter uniformity in chamfer dimensions, allowable inner ring tapered bore deviation and shape error. Average bore diameter variation, outer diameter variation, average outer diameter unevenness as well as raceway width and height variation (for thrust bearings) are also included. Running accuracy constitutes the acceptable values for inner and outer ring radial runout and axial runout, inner ring side runout and outer ring outer diameter runout. All these dimensions of the bearing parts are measured with high-quality equipment.

Bearing life and grease leakage testing

Bearings are run to failure, using accelerated speeds and loads and continuous vibration monitoring. Bearing life testing confirms that any changes to components, materials or the manufacturing process will not negatively impact the bearing's characteristics.

Proper lubrication is a crucial factor in maximizing bearing service life. Contamination can have a great impact on the grease service life and the bearing service life itself. Using high-quality measuring and test equipment, CRAFT bearings conducts grease-leaking and bearing-life research.

General fundamentals

Bearings are inseparable machine components designed to allow rotation between two elements of a mechanism. The weights of the car, the suspension action as well as the driving and braking forces are transmitted over the bearings. That means all the forces are transferred by the miniscule touching areas of the rollers and the inner and outer bearing rings (racers) (**Picture 1**) results in load being applied to the wheel bearing, which must absorb them (**Picture 2**). Not only the bearings have to be covered with the efficient greasing (coat of grease), but also the items must be made from the strongest and the most durable steel which has to be polished and hardened to keep the wear level down to minimum. The seals have a function to prevent the grease leaving the hub and dirt entering the bearing.

Wheel bearings are a very important safety items of a car. The failure of the bearing is usually recognized by the humming sound. However, if wear leads to excessive play, stability may be endangered. In worst cases, the wheel may lock up by seizing rollers, or even come off entirely. Signs of a worn wheel hub bearing vary in severity. Some may be difficult to detect, leading to damage before corrective action can be taken. The timeframe in which damage occurs is linked to driving conditions and/or the mechanical practices that were followed at installation. Noise is a classic sign of a bad wheel bearing or wheel hub bearing. The bearing must be replaced at the earliest stage of failure.

Picture 1 Wheel affecting forces

Picture 2 Forces are transferred into combined loads

TAPERED ROLLER BEARINGS - CRST

CRAFT bearings has bearing designations CRST for tapered roller bearings which have a simple design and posses a huge range for several automotive applications (**Picture 3**). Standard tapered roller bearings consist of an outer race, an inner race with rolling elements and cage. They are normally mounted in pairs. During the installation they are mounted on the shaft in the mirror position, have to be lubricated, sealed and adjusted.

Product advantages:

- High load carrying capacity
- Front and rear wheel
- Simple design

Picture 3 CRST type

DOUBLE ROW ANGULAR CONTACT BALL & TAPERED ROLLER BEARINGS GENERATION 1 HUB - CRB & CRT, DAC & DU

CRAFT bearings has a bearing designation CRB for double row angular contact ball bearings kits and CRT for double row tapered roller bearings kits (**Picture 4**). Also as CRAFT bearings works with different continents and different customers there are requests for several types of products. In this case, CRAFT bearings is able to offer only bearings which designation DAC follows for ball bearing and DU for tapered. Bearing consists of two inner rings, one extended outer ring, cage and the ball set. Some seals of these bearings have an integrated impulse wheel with magnetic particles applied directly to the seal flinger. Mainly used for driven wheels.

Replacement of a Gen 1 bearing can be challenging and labor intensive. The use of specialized tools to facilitate replacement is a must due to the interference fit nature of this style of bearing into the knuckle assembly. The Gen 1 and other bearings are susceptible to damage from the use of an impact gun, both from tightening the axle nut and during the installation of the bearing into the knuckle without the proper tools. Industry experts stress that the leading cause of premature Gen 1 bearing failure is the failure to properly torque the axle nut, even after careful installation.

Product advantages:

- Lubricated for life;
- Defined and preset clearance;
- Integrated impulse wheel in the seal.

Picture 4 CRB & CRT

GENERATION 2 HUB BEARINGS - CRB2 & CRT2

CRAFT bearings has a bearing designation CRB2 for flanged double row angular contact ball bearings and CRT2 for flanged double row tapered roller bearings (**Picture 5**). Gen 2 hub bearings designed with the experience gained from first generation DAC & DU have an outer ring with an integral flange, replacing the function of a separate hub. The flange is tough, with threaded hole or studs to center and mount brake and wheel. Some of them have an impulse wheel as part of the outer ring, produced by cold forming. Typically used with a rotating outer ring for non-driven front or rear wheels.

Assembly of gen 2 hub bearing is made by fixing outer flanged ring to the knuckle and drive shaft is connected to the inner ring. When reassembling, all the mating surfaces and the spindle should be cleaned and lubed with the recommended lubricant, typically a small amount of engine oil. Occasionally a slide hammer or puller may be required to remove the assembly, but care must be taken not to damage the threads on the spindle or the spindle itself.

Product advantages:

- Lubricated for life;
- Easy assembled;
- Defined and preset clearance;
- Arranged sealing.

Picture 5 CRB2 & CRT2

GENERATION 3 HUB BEARINGS - CRB3 & CRT3

The Gen 3 wheel bearing design incorporates two separate flanges and a double row angular contact ball or tapered roller bearing design that are sealed and lubed for life. CRAFT bearings has a bearing designation CRB3 for ball bearings and CRT3 for tapered roller bearings (**Picture 6**). The outer ring flange does not rotate and is attached to the suspension, while the rotating inner ring, with its tough flange, spigot and threaded holes or studs is to locate and retain the wheel. Used for both driven and non-driven wheel applications.

Assembling Gen 3 hub bearings wheel and brake disc are fixed at the flanged inner ring, while outer ring is fixed to suspension.

Product advantages:

- High load carrying capacity;
- Reduced expenses of assembly due to construction of two flanges;
- Easy mounting;
- For front and rear wheels.

Picture 6 CRB3 & CRT3

Features

In regards to grease and its application, there are critical elements used in the formulation process that must be considered. These elements include the thickener type and concentration, lubricant type, viscosity and additive package. Moreover, there are special requirements of wheel-bearing greases that are shown in **Picture 7**. Greases are rated by the National Lubricating Grease Institute (NLGI) and range from 000 through 6. An NLGI 2 grade is typically the specification used in automotive greases. Regardless of the application, greases should reduce friction and wear, protect against corrosion, seal bearings from water and contaminants.

Picture 7 Requirements of wheel - bearing greases

While one of the main reasons for grease failure is selecting the wrong type of grease for the intended application, there may also be other causes, such as incompatibility resulting in excessive softening of the grease, contamination leading to excessive wear or applying too little or too much grease for the application. Over 50 percent of all rolling-bearing defects are due to improper lubrication (see **Chart 1**). In close cooperation with our quality engineers and manufacturing shops we made conclusions and the following greases are used in our automotive bearings: ESSO/MOBIL RONEX MP, SHELL Alvania RL2 (Gadus S2 V100 2), China Hangu No.2 & Kyodo Yushi RareMax AF-1 (**Table 1**)

In order to prevent external dirt or humidity from entering into the bearing and prevent lubricant from leaking out sealing mechanisms are used. The service life of the bearings very often depends on the efficiency of these mechanisms. There are a lot of different types, and various factors must be considered when choosing the right one to be applied:

- Type of lubricant;
- Rotation speed;
- Cost

Some of wheel bearings have a layer of elastomeric material, containing magnetic particles, applied directly on the seal flinger. This type of impulse wheel, integrated into the seal, is difficult to visually identify. The handling of such a bearing has to be done with care as magnetized seal can be easily damaged and this will affect the ABS function.

The bad efficiency or low quality of seals can lead to solid and liquid contamination of lubricant. Solid contamination in the lubricant cause wear and premature fatigue. The harder the ingress contaminant and the smaller the bearing, the more life is reduced. The harmful effect of liquid contaminants in lubricant is often greatly underestimated. Even pure water without additional aggressive media has a very high potential for damage in rolling bearings.

Chart 1 Common causes of rolling-bearings failure

Grease brands	Manufacturer	Thickener	Base Oil
RareMax AF-1	Kyodo Yushi Co	Urea	Mineral
Ronex MP	Exxon/Mobil	Lithium	Mineral
Alvania RL2	Shell	Lithium	Mineral
Hangu No.2	Great Wall	Urea	Mineral

Table 1 Grease brands used in CRAFT Automotive bearings

To avoid these types of contamination following steps can be used :

- Usage of clean lubricants;
- Effective sealing;
- Thorough cleaning of the parts surrounding the bearings;
- Cleanliness during installation.

Common Causes of Wheel Hub Failures

Wheel hub assemblies are designed to require little or no maintenance once they are installed, but that does not mean assemblies cannot fail for a variety of reasons. Some of these failures are associated with actions that take place during the installation process, while others are attributable to weather and road conditions. If you are troubleshooting failures, look to these common root causes for answers.

I Excessive Vehicle Loads - If customers' vehicles are constantly overloaded past recommended carrying capacities, vehicles can end up getting damaged, which includes the failure of wheel hub assemblies. It is important to follow manufacturer guidelines and specifications for the intended use of vehicles.

II Road Hazards - Whether it is a pothole, large rock or some other form of obstruction or deformity, road hazards can damage car wheels and their supporting structures. This includes wheel bearings and wheel hub assemblies, along with other parts in wheel areas.

III Poor Handling - If a customer abuses their vehicle, all sorts of bad things can happen. This includes the misalignment of wheels and tires, along with the damaging of important parts, such as wheel hub assemblies.

It is a known statistical fact that more than 90% of all bearing failures are due to external influences. These include lubrication conditions, assembly installation techniques, contamination of the operating environment, and improper bearing size selection for the application. Under proper operating conditions, a bearing should only fail from fatigue which is predictable based on the bearing size and its application parameters. For that reason, we present this guide as a reference towards understanding the causes and effects of bearing damage:

1. Fatigue spalling

Change in the structure, which is caused by the repeated stresses developed in the contacts between the rolling elements and the raceways.

Figure 1 Fatigue spalling on the raceway

2. Wear

Can be defined as a process where interaction between two surfaces or bounding faces of solids within the working environment results

in dimensional loss of one solid, with or without any actual decoupling and loss of material. Wear can be divided into 2 groups: Adhesive and Abrasive

Figure 2 Adhesion occurs in equipment operating in the mixed and boundary lubrication regimes due to insufficient lube supply, inadequate viscosity, incorrect internal clearances, incorrect installation or misalignment.

Figure 3 Abrasive wear is the result of inadequate lubrication or the ingress of foreign particles.

3. Corrosion

A chemical reaction on metal surfaces. Mostly common appearances of corrosion are: moisture, frictional, fretting and false brinelling corrosions.

Figure 4 Rusting of a bearing inner ring caused by moisture in a lubricant

Figure 5 Fretting corrosion occurs in fit interfaces that are transmitting loads under oscillating contact surface micro-movements.

Figure 6 Localized wear spots made by rolling elements on raceway due to limited rolling/repeated impact are called false brinelling.

4. Electrical erosion

Removal of material from the contact surfaces caused by the passage of electric current. Can be described in 2 types: electrical pitting and electrical fluting

Figure 7 Electrical pitting are small burns created by arcs from improper electric grounding while the bearing is stationary

Figure 8 When electric currents pass through a bearing, there is arcing and burning at the points between the races and the rolling elements where the current jumps the air gap.

5. Plastic deformation

Appears on a bearing whenever the yield strength of the material is exceeded.

Figure 9 Plastic deformation appearance on the raceway after overloading.

Figure 10 Cage deformation

caused by improper installation or dropped bearing.

6. Indentation from debris

A result of contamination during mounting operation or inadequate sealing.

Figure 11 Raceways and rolling elements can incur indentations and nicks caused by hard, possibly sharp, objects.

7. Fracture and cracking

In general are initiated and propagated when the ultimate tensile strength of the material is exceeded

Figure 12 Forced fracture caused by a direct hammer blow.

Figure 13 Thermal cracking is caused by high frictional heating due to sliding motion.
